(54) Title: PROCESS FOR THE POLYMERIZATION OR COPOLYMERIZATION OF ETHYLENE

(57) Abstract

In gas phase polymerizations and copolymerizations of ethylene, reagents or cofeeds control the molecular weight, expressed as MI (wherein MI is measured according to ASTM D-1238 Condition E), of the resin product. Use of isopentane and electron donating compounds reduce MI; whereas, water and electron withdrawing compounds increase MI.

Process for the Polymerization or
Copolymerization of Ethylene

This invention relates to a process for the polymerization
5 or copolymerization of ethylene.

Polyethylene is produced commercially in a gas phase
reaction in the absence of solvents by employing selected
chromium and titanium-containing catalysts under specific
operating conditions in a fluid bed process. Polyethylene
10 products of such commercial processes exhibit medium-to-broad
molecular weight distribution. To be commercially useful in the
gas phase fluid bed process, or a slurry reactor process,
undertaken at low pressures, e.g. of less than about 1000 psi,
the catalyst must exhibit high activity, with concomitant high
15 catalyst productivity, because these process systems do not
include catalyst residue removal procedures. Accordingly,
catalyst residue in the polymer product must be so small that
it can be left in the polymer without causing any undue problems
in the fabrication and/or to the ultimate consumer.

20 The need for new catalysts lead to the development of
metallocene compounds of transition metals as catalysts for
polymerization and copolymerization of ethylene. Metallocenes
can be described by the empirical formula $Cp_mMA_nB_p$. These
compounds in combination with alumoxane have been used to
25 produce olefin polymers and copolymers, such as ethylene and
propylene homopolymers, ethylene-butene and ethylene-hexene
copolymers: see, for example US-A-4542199 and US-A-4404344.

Methylalumoxane (MAO) is commonly used as co-catalyst with
metallocene catalysts. It belongs to the class of alumoxanes
30 which comprises oligomeric linear and/or cyclic alkylalumoxanes
represented by the formula:

$R-(Al(R)-O)_n-AlR_2$ for oligomeric, linear alumoxanes and

$(-Al(R)-O-)_m$ for oligomeric cyclic alumoxane

wherein n is 1-40, preferably 10-20, m is 3-40, preferably 3-20

35 and R is a C_1-C_8 alkyl group and preferably methyl.

Methylalumoxane is commonly produced by reacting
trimethylaluminum with water or with hydrated inorganic salts,

- 2 -

such as $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ or $\text{Al}_2(\text{SO}_4)_3 \cdot 5\text{H}_2\text{O}$. Methylalumoxane can be also generated in situ in polymerization reactors by adding to them trimethylaluminum and water or water-containing inorganic salts. MAO is a mixture of oligomers with a very wide distribution of
5 molecular weights and usually with an average molecular weight of about 1200. MAO is typically kept in solution in toluene. While the MAO solutions remain liquid at fluid bed reactor temperatures, the MAO itself is a solid at room temperature.

Most of the experiments reported in the literature relating
10 to methylalumoxane used as a cocatalyst with metallocene catalysts are undertaken in a slurry or solution process, rather than in a gas phase fluid bed reactor process.

It is desirable to control the MI of the polymerisation products, because such control provides a method of meeting
15 target molecular weights, which vary for different applications. Generally, a low MI product is used for producing tough films. However, depending on the fabrication means and method, polyethylene (and its copolymers) of different MI will be required. For example for blown film production, the
20 polyethylene target MI ranges from 0.6 to about 2. By comparison, for cast film production the polyethylene target MI ranges from 2.5 to 3.5. When the application is injection moulding, and target MI ranges up to 150, usually from 10 to 120, hydrogen may be used to control MI.

25 The present invention is predicated upon the discovery that certain reagents can alter the MI of the polymerized product: more specifically, isopentane and electron donating compounds lead to a decrease in MI; and water and electron withdrawing compounds leads to an increase in MI.

30 This discovery enables control of the polymerization process to adjust MI.

According to the present invention, there is provided a process for the polymerization of ethylene or the copolymerization of ethylene with an alpha olefin of 3 to 10
35 carbon atoms, produces resin having a MI (g/10 min.) value in the range of 0.0001 to 500, (wherein MI is , wherein the process comprises:

- 3 -

- (a) fluidizing a particulate, activated supported metallocene catalyst, in a fluid bed gas phase reactor, wherein the catalyst comprises a support, a transition metal (M_{Tr}) and Al, wherein the amount of M_{Tr} (elemental basis) ranges from 0.001 to 10 weight percent, the amount Al (elemental basis) ranges from 1 to 40 weight percent and the Al: M_{Tr} ratio (elemental basis) ranges from 25 to 10000;
- (b) contacting said catalyst with a feed selected from the group consisting of (1) ethylene, (2) ethylene admixed with hydrogen, (3) ethylene admixed with an alpha olefin of 3 to 10 carbon atoms, and (4) ethylene admixed with hydrogen and an alpha olefin of 3 to 10 carbon atoms, to produce polymerized product;
- (c) maintaining a polymerization pressure of less than 1000 psi (6.9 MPa) and a polymerization temperature in the range of 55°C to 115°C;
- (d) contacting the fluidized catalyst with a reagent to increase or decrease the MI of the polymerized product; and
- (e) recovering polymerized product.

It may be possible to operate the polymerization temperature in the range 50°C to 115°C.

In one embodiment the reagent is isopentane and/or an electron donating compound to decrease the MI of the polymerized product. Preferably, the isopentane is used at a partial pressure of from 2 to 80 psi (14 to 550 KPa).

Preferably, the electron donating compound is used in an amount ranging from 0.01 to 500 ppm molar ratio to ethylene.

Desirably, the electron donating compound is selected from the group consisting of oxygen, carbon monoxide and carbon dioxide.

It is preferred that the isopentane is co-fed with the electron donating compound, which is selected from the group consisting of oxygen, carbon monoxide and carbon dioxide.

In another embodiment the reagent is water and/or an electron withdrawing compound to increase the MI of the

- 4 -

polymerized product.

The invention is applicable to high or low pressure gas phase processes (but with pressure < 1000 psi [6.9 Mpa]), in which molecular weight control of olefin polymers (or 5 copolymers), produced in the presence of a metallocene catalyst, is effected by controlling the MI of the resulting polymer.

In a preferred embodiments, the process is undertaken in a low pressure fluid bed process for catalytic polymerization or copolymerization of ethylene, in the presence of metallocene 10 catalysts.

The catalyst is a supported catalyst, wherein the support is preferably silica, alumina or silica/alumina: the support is preferably also amorphous and porous. In the preferred catalyst the support is silica.

15 The MI can additionally be controlled by controlling the polymerization temperature within said range of 55°C to 115°C, the polymerization temperature being selected to be at the higher end of the range to produce product of relatively low MI, and the polymerization temperature being selected to be at the 20 lower end of the range to produce product of relatively high MI.

For increasing the MI of products produced during the polymerization process, the temperature of polymerization is decreased. Thus, if the product MI would be about 0.02 and the need for increasing the product MI above 0.02 is present, then 25 the polymerization is undertaken at temperatures at the lower end of the range of 55°C to 115°C.

For example, the temperature may have to be above 65°C to produce a product MI of less than 4, above 70°C to produce a product MI of less than 3 and above 75-80°C to produce a product 30 MI of less than 2. Conversely, the temperature may have to be below 100°C to produce a product MI of greater than 0.5, below 90°C to produce a product MI of greater than 1 and below 75-80°C to produce a product MI of greater than 2.

The polymerization temperature may be in the range 65 to 35 90°C, preferably 75 to 80°C.

The polymerization product according to the invention generally has a MI in the range 0.0001 to 500, preferably 0.1

- 5 -

to 500, more preferably 0.1 to 200. Of particular interest are products having a MI in the range of 0.02 to 20.0. It is especially preferred that the MI is in the range of 0.05 to 10, particularly 0.05 to 5.

5 In accordance with another aspect of the invention there is provided a polymerization product made by the process defined above, said product having a MI less than 500, a settled bulk density in the range of 22 to 36 lb/ft³ (350 to 580 kg/m³) and a density less than 0.94 g/cm³.

10 For decreasing the MI of products produced during the polymerization process, the temperature of polymerization is increased. Thus, if the product MI would be about 10 and the need for decreasing the product MI is present, then the polymerization is undertaken at temperatures at the higher end
15 of the range of 55°C to 115°C. The temperature range of the process is dependent on the product density. For example, 60 to 90°C is typical for low density (<0.930) products.

As described above, the reagents which are used to decrease MI are electron donating in effect: a preferred group of
20 reagents include oxygen and organic compounds containing oxygen atoms. The reagents which are used to increase MI are electron withdrawing in effect.

In the process according to the invention, the activated catalyst is fluidized by diffusing gas, e.g., recycle gas,
25 through the bed at a rate sufficient to maintain fluidization. Fluidization can be achieved by a high rate of gas recycle to and through the bed, typically in the order of about 200 times the rate of feed of make-up gas.

The olefin feed to the reaction zone of the polymerization
30 reactor comprises ethylene. Ethylene polymers, as well as copolymers of ethylene with one or more C₃-C₁₀ alpha-olefins, can be produced in accordance with the invention. Thus, copolymers having two monomeric units are possible as well as terpolymers having three monomeric units. Particular examples of such
35 polymers include ethylene/1-butene copolymers, ethylene/1-hexene copolymers and ethylene/4-methyl-1-pentene copolymers. Ethylene/1-butene and ethylene/1-hexene copolymers are the most

- 6 -

preferred copolymers polymerized in the process of and with the catalyst of this invention.

The ethylene copolymers produced in accordance with the present invention preferably contain at least about 80 percent
5 by weight of ethylene units. The catalyst of this invention may be used to polymerize propylene and other alpha-olefins and to copolymerize them. Preferably, the polymerization (copolymerization) is undertaken at a temperature and/or pressure below the sintering temperature of the polymer
10 particles.

In the general type of polymerization process described herein, pressures are below 10000 psi (69MPa), preferably below 1000psi (6.9 MPa). In low pressure polymerization pressures of up to about 1000 psi (6.9 MPa) are employed.

15 In accordance with the invention, the fluid bed reactor is operated at pressures of up to about 1000 psi (6.9 MPa). In low pressure polymerization carried out in accordance with the process of the invention pressures are below 400 psi (2.8 MPa), and preferably operation is at a pressure of from about 150 to
20 350 psi (1 to 2.4 MPa); operation at the higher pressures in such ranges favours heat transfer, since an increase in pressure increases the unit volume heat capacity of the gas. The high activity of the catalysts allow for efficacious low pressure fluid bed gas phase polymerizations.

25 Much lower activity catalysts may be employed in high pressure processes at pressures which exceed 400 psi (2.8 MPa), such as solution and high pressure slurry polymerizations.

For the production of ethylene copolymers in the process of the present invention an operating temperature of about 55°
30 to 115°C is used. Generally, temperatures of 60° to 90°C are used to prepare products having a density of 0.91 to 0.92; temperatures of 70° to 100°C are used to prepare products having a density of 0.92 to 0.94, and temperatures of 80° to 115°C are used to prepare products having a density of 0.94 to 0.96.

35 The partially or completely activated catalyst is preferably injected into the fluid bed at a point above the distribution plate at a rate equal to its consumption. Since

- 7 -

the catalysts used in the practice of this invention are highly active, injection of the fully activated catalyst into the area below the distribution plate may cause polymerization to begin there and eventually cause plugging of the distribution plate.

5 Injection into the bed, instead, aids in distributing the catalyst throughout the bed and precludes the formation of localized spots of high catalyst concentration.

The production rate of polymer in the bed is controlled by the steady state rate of catalyst and monomer injection. Since

10 any change in the rate of catalyst injection changes the rate of generation of the heat of reaction, the temperature of the recycle gas is adjusted to accommodate the change in rate of heat generation. Complete instrumentation of both the fluidized bed and the recycle gas cooling system is, of course, necessary

15 to detect any temperature change in the bed so as to enable the control system to make a suitable adjustment in the temperature of the recycle gas. Since the rate of heat generation is directly related to product formation, a measurement of the temperature rise of the gas across the reactor (the difference

20 between inlet gas temperature and exit gas temperature) is determinative of the rate of particulate polymer formation at a constant gas velocity.

The reagents which are used to decrease MI, compared to the MI of products produced in the absence of said reagents, are

25 isopentane and compounds which are electron donating in effect.

Electron donating compounds which have been used and which do decrease MI include oxygen, carbon dioxide, carbon monoxide. A preferred group of reagent compounds which are electron donating in effect include organic compounds which include

30 oxygen atoms. Electron donating reagents which may be used include CO, CO₂, NO, NO₂, N₂O ethers, alcohol, peroxides, ketones, esters, thioethers, amines, phosphines, phosphine oxides, and phenols.

The general formulas for these electron donating reagents

35 are: ROR¹, ROH, ROOR¹, RCOR¹, RCOOR¹, RSR¹, RR¹R²N, RR¹R²P, RR¹R²PO where

R-CH₃, C₂H₅, n-C₃H₇, i-C₃H₇, n-C₄H₉, i-C₄H₉, t-C₄H₉, C₆H₅ or

- 8 -

other alkyl substituted aryl group;

Where R^1 and R^2 may be the same or different, and may be H, CH_3 , C_2H_5 , $n-C_3H_7$, $i-C_3H_7$, $n-C_4H_9$, $i-C_4H_9$, $t-C_4H_9$, C_6H_5 or other alkyl substituted aryl group.

5 These reagents are added in amounts effective to change the MI of the product by decreasing it. In a gas phase, fluid bed reactor the olefin feed is in the presence of about 0.01 to about 1000 ppm molar ratio of these compounds, calculated on the basis of ethylene feed. This compound can be injected into the
10 reaction (polymerization zone) or added as a co-feed, or admixed with recycle gas, or fed into any other feed stream.

Reagents including water and those containing electron withdrawing atoms have also been employed to control MI by increasing MI and include trialkylaluminum, e.g.,
15 trimethylaluminum, triethylaluminum, triisobutylaluminum, alkylaluminum chloride, trialkyl borane, and dialkylmagnesium. Some representative formulas are: R_2Mg , $RMgCl$, R_3Al , R_3B , R_2AlCl , R_2BCl , $RAI Cl_2$, $RBCl_2$, $R_3Al_2Cl_3$, $R_3B_2Cl_3$, where R may be H, CH_3 , C_2H_5 , $n-C_3H_7$, $i-C_3H_7$, $n-C_4H_9$, $i-C_4H_9$, $t-C_4H_9$, C_6H_5 or other alkyl
20 group, or aryl group, or substituted aryl group. These reagents are added in amounts effective to change the MI of the product by increasing it.

Note that although these reagents can change MI, they do not increase fines production.

25 In a gas phase, fluid bed reactor, the olefin feed is in the presence of about 10 to about 1000 ppm molar ratio of these compounds, calculated on the basis of ethylene feed. In addition to increasing MI the reagent does not increase fines
production. This compound can be injected into the reaction
30 (polymerization zone) or added as a co-feed, or admixed with recycle gas, or injected with a comonomer.

Hydrogen may be used as a chain transfer agent in the polymerization reaction of the present invention. The ratio of hydrogen/ethylene employed will vary from 0 to 2, preferably 0
35 to 0.5, moles of hydrogen per mole of ethylene in the gas phase. Any gas inert to the catalyst and reactants can also be present in the gas stream.

- 9 -

Reference is now made to the accompanying drawing, Figure 1, which is a schematic drawing of a gas phase fluid bed reactor for olefin polymerization or copolymerization, for use in the process according to the present invention.

5 In Figure 1, a reactor 10 consists of a reaction zone 12, a velocity reduction zone 14 and a distributor plate 20. Although fouling can occur in all of the cold areas (areas in a reactor at a temperature which is less than the temperature at which any component in the gas phase reactor are liquid
10 rather than gaseous) distributor plate fouling is the one most easily detected, since it results in a rapid increase in the pressure drop across the distributor plate due to flow restriction. Such flow restrictions also result in changing fluidization patterns and contribute to reactor operating
15 problems.

The lowest temperature in the reactor loop is in the reactor inlet beneath the distributor plate. Other areas representing the coldest sections in the fluid bed reactor system include the cooler and piping between the cooler and the
20 bottom head.

The reaction zone 12 comprises a bed of growing polymer particles and a minor amount of catalyst particles fluidized by the continuous flow of polymerizable and modifying gaseous components. To maintain a viable fluidized bed, the mass gas
25 flow rate through the bed must be above the minimum flow required for fluidization, and preferably from about 1.5 to about 10 times G_{mf} and more preferably from about 3 to about 6 times G_{mf} . G_{mf} is used in the accepted form as the abbreviation for the minimum mass gas flow required to achieve fluidization,
30 C. Y. Wen and Y. H. Yu, "Mechanics of Fluidization", Chemical Engineering Progress Symposium Series, Vol. 62, p. 100-111 (1966).

The distribution plate 20 serves the purpose of supporting the bed and distributing recycle gas through the bed at a rate
35 sufficient to maintain fluidization of the bed. Fluidization is achieved by a high rate of gas recycle to and through the bed, typically in the order of 50 to 200 times the rate of feed

- 10 -

of make-up gas. Make-up gas is fed to the bed at a rate equal to the rate at which particulate polymer product is formed by reaction plus any vent or other losses. The composition of the make-up gas is determined by a gas analyzer usually piped across
5 the compressor. The composition of the make-up gas is continuously adjusted to maintain an essentially steady state gaseous composition within the reaction zone.

The portion of the gas stream which does not react in the bed (the recycle gas) passes a velocity reduction zone 14, where
10 entrained particles are given an opportunity to drop back into the bed, and is compressed in a compressor 25; the gas stream then passes through a heat exchanger 26 and is returned to the bed.

The distribution plate 20 serves the purpose of diffusing
15 recycle gas through the bed at a rate sufficient to maintain fluidization. The plate may be a screen, slotted plate, perforated plate, a plate of the bubble cap type, and the like. The elements of the plate may all be stationary, or the plate may be of the mobile type disclosed in US-A-3298792.

20 Under a given set of operating conditions, the fluidized bed is maintained at essentially a constant height by withdrawing a portion of the bed as product at a rate equal to the rate of formation of the particulate polymer product. The catalyst is injected into the bed at a point above the
25 distribution plate at a rate equal to its consumption. Injection of the catalyst is via a catalyst feeder. Since the catalysts used in the practice of this invention are highly
active, injection of the fully activated catalyst into the area below the distribution plate may cause polymerization to begin
30 there and eventually cause plugging of the distribution plate. Injection into the bed, instead, aids in distributing the catalyst throughout the bed and precludes the formation of localized spots of high catalyst concentration.

The catalyst used in the invention comprise a carrier, an
35 alumoxane and at least one metallocene. The catalyst is desirably free-flowing and particulate in form comprising dry powder particles having a particle size of from about 1 micron

- 11 -

to about 250 microns, preferably from about 10 microns to about 150 microns. The catalysts which contain only one transition metal in the form of a metallocene have an activity of at least about 200 kg polymer/g of transition metals. The aluminoxane and metallocene loading on the carrier is such that the amount of aluminum, (elemental basis) provided by the aluminoxane, on the carrier ranges from 1 to 40 weight percent, preferably from 5 to 30 weight percent, and most preferably from 5 to 15 weight percent. The optimum MAO loading is in the range of 3 to 15 mmoles of aluminum per gram of silica carrier; if a silica carrier is overloaded with MAO, the catalyst activity is lower and the catalyst particles agglomerate with attendant problems of transferring the catalyst.

The amount of metallocene on the carrier ranges, on a transition metal (M_{Tr}) elemental basis, from 0.001 to 10 weight percent, preferably from 0.01 to 1.0, and most preferably from 0.05 to 0.4 weight percent. Accordingly the ratio of Al: M_{Tr} (on an elemental basis) in the catalyst can range from 25 to 10,000, usually within the range of from 50 to 1000 but preferably from about 75 to 500, and most preferably from 100 to 200.

To form catalysts of the invention, all catalyst components can be dissolved with alumoxane and impregnated into the carrier. Catalyst preparation can be undertaken under anhydrous conditions and in the absence of oxygen. In a process described below, the carrier material is impregnated with alumoxane, preferably methylalumoxane. The class of alumoxanes comprises oligomeric linear and/or cyclic alkylalumoxanes represented by the formula: $R-(Al(R)-O)_n-AlR_2$ for oligomeric, linear alumoxanes; and $(-Al(R)-O)_m$ for oligomeric cyclic alumoxane wherein n is 1-40, preferably 10-20, m is 3-40, preferably 3-20, and R is a C_1-C_8 alkyl group and preferably methyl.

MAO is a mixture of oligomers with a very wide distribution of molecular weights and usually with an average molecular weight of about 1200. MAO is typically kept in solution in toluene.

The volume of the solution comprising an alumoxane and a solvent therefor can vary, depending on the catalyst sought to

- 12 -

be produced. In a preferred embodiment of alumoxane incorporation into the carrier, one of the controlling factors in the alumoxane incorporation into the carrier material catalyst synthesis is the pore volume of the silica. In this preferred embodiment, the process of impregnating the carrier material is by infusion of the alumoxane solution, without forming a slurry of the carrier material, such as silica, in the alumoxane solution. This is undertaken with agitation. The volume of the solution of the alumoxane is sufficient or less than that required to fill the pores of the carrier material without forming a slurry in which the volume of the solution exceeds the pore volume of the silica; preferably, the maximum volume of the alumoxane solution does not exceed the total pore volume of the carrier material sample: this maximum volume of the alumoxane solution ensures that no slurry of silica in solvent is formed in this step.

By way of example, if the pore volume of the carrier material is $1.65 \text{ cm}^3/\text{g}$, then the volume of alumoxane will be equal to or less than $1.65 \text{ cm}^3/\text{g}$ of carrier material. Thus, the maximum volume of solution (of metallocene and alumoxane) will equal the total pore volume of the carrier, e.g. silica, which is the pore volume in, e.g., cm^3/g , times the total weight of the carrier used. As a result of this provision, the impregnated carrier material will appear dry immediately following impregnation although the pores of the carrier may be filled with inter alia solvent. The preferred solvent for the aluminoxane, e.g. methylaluminoxane, is toluene. The advantage is that the impregnation is undertaken in a single solvent system.

Solvent may be removed from the alumoxane impregnated pores of the carrier material by heating and/or under a vacuum or purged with heating in an inert gas, such as nitrogen. If elevated temperature is employed, the temperature conditions in this step are controlled to reduce, if not to eliminate, agglomeration of impregnated carrier particles and/or crosslinking of the alumoxane. In this step, solvent can be removed by evaporation effected at relatively low elevated

- 13 -

temperatures in the range of 40 to 60°C to obviate agglomeration of catalyst particles and crosslinking of the alumoxane.

Preferably drying is undertaken at 45°C or less for 5 to 7 hours. Although solvent can be removed by evaporation at relatively higher temperatures than the 40 to 60°C range described above, very short heating times schedules must be employed to obviate agglomeration of catalyst particles and crosslinking of the alumoxane, with reduction of catalyst activity. Thus, an active catalyst has been produced at evaporation temperature of 110°C in less than 10 seconds (at extremely short heating times), whereas at 45°C, drying can be undertaken for periods of 24 hours. A vacuum can be employed to facilitate drying.

In a preferred embodiment, the metallocene is added to the solution of the alumoxane prior to impregnating the carrier with the solution. Again the maximum volume of the alumoxane solution also containing the metallocene is the total pore volume of the carrier material sample. The mole ratio of aluminum provided by aluminoxane, expressed as Al, to metallocene metal expressed as M (e.g. Zr), preferably ranges from 50 to 1000, preferably 75 to 500, and most preferably 100 to 200. The Al:M_T ratio can be directly controlled.

In a preferred embodiment the alumoxane and metallocene compound are mixed together at ambient temperature for 0.1 to 6.0 hours, prior to use in the infusion step. The solvent for the metallocene and alumoxane can be appropriate solvents, such as aromatic hydrocarbons, halogenated aromatic hydrocarbons, ethers, cyclic ethers or esters; preferably it is toluene.

The metallocene compound has the formula $Cp_mMA_nB_p$ in which Cp is an unsubstituted or substituted cyclopentadienyl group, M is zirconium or hafnium and A and B belong to the group including a halogen atom, hydrogen or an alkyl group. In the above formula of the metallocene compound, the preferred transition metal atom M is zirconium.

In the above formula for the metallocene compound, the Cp group is a mono- or a polysubstituted cyclopentadienyl group. The substituents on the cyclopentadienyl group can be preferably

- 14 -

straight-or branched chain C_1-C_6 alkyl groups. The cyclopentadienyl group can be also a part of a bicyclic or a tricyclic moiety such as indenyl, tetrahydroindenyl, fluorenyl or a partially hydrogenated fluorenyl group, as well as a part of a substituted bicyclic or tricyclic moiety. In the case when m in the above formula of the metallocene compound is equal to 2, the cyclopentadienyl groups can be also bridged by polymethylene or dialkylsilane groups, such as $-CH_2-$, $-CH_2-CH_2-$, $-CR'R''-$ and $-CR'R''-CR'R''-$ where R' and R'' are short alkyl groups or hydrogen, $-Si(CH_3)_2-$, $Si(CH_3)_2-CH_2-CH_2-Si(CH_3)_2-$ and similar bridge groups. If the A and B substituents in the above formula of the metallocene compound are halogen atoms, they belong to the group of fluorine, chlorine, bromine or iodine. If the substituents A and B in the above formula of the metallocene compound are alkyl groups, they are preferably straight-chain or branched C_1-C_8 alkyl groups, such as methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, n-pentyl, n-hexyl or n-octyl.

Suitable metallocene compounds include bis(cyclopentadienyl)metal dihalides, bis(cyclopentadienyl)metal hydridohalides, bis(cyclopentadienyl)metal monoalkyl monohalides, bis(cyclopentadienyl)metal dialkyls and bis(indenyl)metal dihalides wherein the metal is zirconium or hafnium, halide groups are preferably chlorine and the alkyl groups are C_1-C_6 alkyls. Illustrative, but non-limiting examples of metallocenes include bis(n-butylcyclopentadienyl)zirconium dichloride, bis(n-butylcyclopentadienyl)hafnium dichloride, bis(n-butylcyclopentadienyl)zirconium dimethyl, bis(n-butylcyclopentadienyl)hafnium dimethyl, bis(n-butylcyclopentadienyl)zirconium hydrido-chloride, bis(n-butylcyclopentadienyl)hafnium hydrido-chloride, bis(iso-butylcyclopentadienyl)zirconium dichloride, bis(pentamethylcyclopentadienyl)zirconium dichloride, bis(pentamethylcyclopentadienyl)hafnium dichloride, bis(iso-butylcyclopentadienyl)zirconium dichloride, cyclopentadienyl-zirconium trichloride, bis(indenyl)zirconium dichloride, bis(4,5,6,7-tetrahydro-1-indenyl)zirconium dichloride, and ethylene-[bis(4,5,6,7-tetrahydro-1-indenyl)] zirconium

- 15 -

dichloride.

The metallocene compounds utilized within the embodiment of this art can be used as crystalline solids, as solutions in aromatic hydrocarbons or in a supported form.

5 The carrier material is preferably a solid, particulate, porous, preferably inorganic material, such as an oxide of silicon and/or of aluminum. In the most preferred embodiment, the carrier is silica in the form of spherical particles, e.g., as obtained by a spray-drying process. The carrier material is
10 preferably used in the form of a dry powder having a particle size of from about 1 micron to about 500 microns, preferably from about 1 micron to about 250 microns, and most preferably about 10 microns to about 150 microns. If necessary, the final catalyst containing carrier material may be sieved to ensure
15 elimination of large catalyst particles. Presently, elimination of catalyst particles that have a particle size of greater than 500 microns is envisaged; preferably, elimination of particles of greater than 250 micron particle size, and, most preferably, elimination of particles of greater than 150 micron particle
20 size is undertaken. Sieving of the material is preferably undertaken after impregnation of the carrier with the metallocene and the aluminoxane. This is particularly desirable when the catalyst contains only one transition metal in the form of a metallocene and which is used to form narrow molecular
25 weight LLDPE, to reduce and/or to eliminate gels in the final polyolefin product and to eliminate reactor hot spots, thereby ensuring reactor continuity, particularly in the gas phase fluid bed process.

The surface area of the carrier is preferably at least 3
30 m^2/g , preferably, 5 to $1200 \text{ m}^2/\text{g}$ and most preferably at least about $50 \text{ m}^2/\text{g}$ up to about $350 \text{ m}^2/\text{g}$. The pore volume of the carrier will usually range from 0.1 to $5 \text{ cm}^3/\text{g}$, preferably from 0.1 to $3.5 \text{ cm}^3/\text{gm}$. The carrier material should preferably be dry, that is, free of absorbed water.

35 Preferably, the carrier is silica, which contains [OH] groups. The hydroxyl group of the silica may range from greater than 0.5 mmole/g silica to 2.5 mmole/g silica. This range is

- 16 -

favoured by lower drying, dehydration and/or calcination temperatures.

The silica hydroxyl (herein silanol, silica hydroxy and silica hydroxyl are used interchangeably) groups are detectable by IR spectroscopy. Quantitative determinations of the hydroxyl concentration on silica are made by contacting a silica sample with methyl magnesium iodide and measuring methane evolution (by pressure determination).

Dehydration of silica material can be effected by heating at 100°C to 600°C, preferably from 150°C to 300°C and most preferably at 250°C.

Silica dehydrated at 600°C (for about 16 hours) will have a surface hydroxyl concentration of about 0.7 mmole/g silica. Silica dehydrated at 800°C will be a silica with 0.5 mmole of silica hydroxy per gram silica. The silica of the most preferred embodiment is a high surface area, amorphous silica (surface area = 300 m²/g; pore volume of 1.65 cm³/g), and it is a material marketed under the tradenames of Davison 952 or Davison 955 by the Davison Chemical Division of W. R. Grace and Company. As purchased, the silicas are not dehydrated and must be dehydrated prior to use.

The effect of silica hydroxyl groups on the catalyst activity and productivity is reflected in the Examples below. To produce the highest activity catalysts the silica should contain hydroxyl groups for contact with the solution containing aluminoxane and metallocene. It has been determined that reaction of the hydroxyl groups of the silica with scavengers, such as trialkylaluminum compounds, e.g., trimethylaluminum (TMA), reduced the activity of the catalyst produced thereby compared to a catalyst formed with a silica having hydroxyl groups unreacted with such a scavenger. Silicas containing higher hydroxyl numbers produce catalysts of higher activity than silicas of lower hydroxyl numbers. Treating the silica with trimethylaluminum to react with the silanol or silica hydroxy groups [which, with appropriate molar amount of TMA, the hydroxyl concentration is reduced to 0 (zero) as indicated by IR] prior to catalyst synthesis produced a catalyst with a

- 17 -

productivity of about 200 kg(polymer)/g transition metal. However, this activity is good activity, and the catalyst exhibiting such activity is useful in the processes herein. By comparison, catalysts with a hydroxyl group content of 1.8 mmole/g silica exhibits a productivity of more than 1000 kg(polymer)/g transition metal. The amount of hydroxyl groups, in mmole/g silica can be affected by the dehydration temperatures used to condition the silica. Specifically, the dehydration temperatures of about 600°C reduce the amount of reactive hydroxyl groups available for contact with the solution of aluminoxane and metallocene. By comparison, dehydration temperatures of about 250°C increase the amount of reactive hydroxyl groups available for contact with the solution of aluminoxane and metallocene, relative to the silica heat treated, for dehydration purposes, to 600°C. Thus it has been found that the catalyst made with the silica subjected to dehydration temperatures of 250°C is more active than a catalyst produced with the silica subjected to drying temperatures of 600°C. Accordingly, preferred dehydration and/or calcination temperatures are below 300°C and preferably at 250°C.

Accordingly, the silica used in embodiments of the invention will advantageously contain a silanol concentration of greater than 0.7 mmole OH per g silica; preferably it will contain greater than 0.7 mmole up to 2.5 mmole OH per g of silica. In preferred embodiments, the concentration ranges from 1.6 to 2.0 mmole/g silica.

Both low density (0.88 to 0.939 g/cm³) and high density (0.94 to 0.965 g/cm³ and above) products with high bulk density, low (hexane) extractables and granular morphology can be prepared in the slurry or gas phase reactor with no fouling. The resin produced has a high molecular weight, narrow molecular weight distribution, and homogeneous branching distribution. The catalyst ash contains small amounts of Transition metal (eg Zr) and Al: for example, less than 1 ppm transition metal and 100 ppm Al. The high activity of the catalysts of the invention which also exhibit long catalyst life and produce high bulk density products are significant factors in the unexpected

- 18 -

efficacy of these catalysts in catalytic polymerizations and copolymerizations of olefins.

Ethylene polymers, as well as copolymers of ethylene with one or more C₃-C₁₀ alpha-olefins, can be produced in accordance with the invention. Thus, copolymers having two monomeric units are possible as well as terpolymers having three monomeric units. Particular examples of such polymers include ethylene/1-butene copolymers, ethylene/1-hexene copolymers and ethylene/4-methyl-1-pentene copolymers.

10 Ethylene/1-butene and ethylene/1-hexene copolymers are the most preferred copolymers polymerized in the process of and with the catalyst of this invention. The ethylene copolymers produced in accordance with the present invention preferably contain at least about 80 percent by weight of ethylene units.

15 In one embodiment, the catalyst of the invention exhibits high activity for polymerization of ethylene and higher alpha-olefins and allows the synthesis of ethylene polymers and copolymers with a relatively narrow molecular weight distribution and homogeneous branching distribution. The
20 molecular weight distribution is determined as MFR (melt flow ratio of I_{21}/I_2 - wherein I_{21} is measured at 190°C in accordance with ASTM D-1238, Condition F, and I_2 is measured in accordance with ASTM D-1238, Condition E]) which ranges from 15 to 25, in polymerizations of the invention. Branching distribution in
25 ethylene copolymers is evaluated on the basis of the resin's melting point. Relatively homogeneous branching distribution is one which the melting point ranges from 100 to 120°C, depending on comonomer composition. In this embodiment, the catalyst of the invention contains only one source of transition
30 metal, a metallocene. More particularly, the copolymer products contain 0.1 to 2 ppm of Zr. The product has an average particle size of 0.015-0.035 inches (0.38 to 0.89 mm), settled bulk density from 22 to 36 lb/ft³ (350 to 580 kg/m³). The narrow molecular weight distribution low density copolymers can
35 been produced with MI from one to 500 and less than 1, down to 0.0001. The low density products of the invention exhibit a MI which can range from 0.0001 to 500, preferably from 0.1 to 500,

- 19 -

more preferably from 0.1 to 200. One particularly preferred range of MI is 0.5 to 5.0. The low density products of the invention preferably exhibit a melt flow ratio (MFR) of 15 to 25, more preferably from 14 to 20; products with MFR ranging 5 from 16 to 18 have been made.

When films fabricated from the polymers produced by the process of the invention exhibit balanced tear strength, as measured by ASTM D-1922. Furthermore the LLDPE produced by the invention exhibits Dart Drop Impact values as measured by ASTM 10 D-1709 of greater than 800. The products of the catalysis with the catalyst of the invention are substantially free of gels. The films exhibit very low haze values as measured by ASTM D-1003, preferably in the range of 3 to 10, more preferably from 5 to 7. The catalyst ash typically contains less than 1 ppm 15 transition metal (eg Zr) and less than 40 ppm Al.

Because of the excellent comonomer incorporation of the catalyst and the branching homogeneity of the resin, significant amount of hexene saving can be achieved.

MAO (methylalumoxane) is commercially available from Ethyl 20 Chemical and WITCO (previously Schering Berlin) as 10 weight percent and 30 weight percent solutions, which were the sources of MAO used in the Examples.

Examples

25

Preparation of Catalyst A

This catalyst was prepared using silica treated with TMA. PQ 988 IM silica was dehydrated at 600°C for 4 hours. 486 g of this dehydrated silica were reacted with 517 cm³ of 30 trimethylaluminum (14.8 wt% Al) and dried to a white powder at 80°C.

6.90 g of bis(n-butylcyclopentadienyl) zirconium dichloride, 470 ml of toluene, and 649.7 g of methylaluminoxane (14.1 wt% Al in toluene) were mixed together until the Zr 35 complex dissolved. This catalyst solution was then added slowly into the silica previously treated with trimethylaluminum. The contents were agitated vigorously to make sure the reagent

- 20 -

solution was well-dispersed among the silica support.

The mixture was dried at 45°C for 6 hours until a free flowing powder was obtained. The catalyst was not sieved.

5 Preparation of Catalysts B to I

These catalysts were prepared using silica without TMA treatment.

Catalyst B: Davison 955 silica was dehydrated at 600°C for 4 hours. 500 g of this dehydrated silica were then reacted with
10 a solution of 7.084 g of (n-butylCp)₂ZrCl₂ dissolved in 677.6 g of MAO (14.1 wt% Al) in toluene. The Al/Zr molar ratio was 200:1. The catalyst was dried under flowing N₂ at 45°C for 6 hours, and was sieved to remove any particles larger than 150 microns.

15 Catalyst C: Catalyst C was prepared in similar manner to Catalyst B, except that the drying time was 5 hours.

Catalysts D, E, F, G and H: These catalysts were prepared in similar manner to Catalyst C.

Catalyst 8: This catalyst was prepared in similar manner
20 to Catalyst C, except that Davison 955 silica was dehydrated at 250°C.

Gas phase pilot plant reactor results

The above catalysts were used in the pilot plant fluid bed
25 reactor (13 inch (0.33m) internal diameter, 4ft³ (0.11m³) reaction zone) to evaluate their operability and responses to different process variables. Good reactor operability was achieved after a few adjustments were made to the reactor operating parameters. The catalysts used in this work can be
30 divided into two types based upon the difference in activity. The Catalyst A fits into the low activity group while all the others fit into the higher activity group. All the catalysts in the high activity group should be considered the same for the below discussion.

35 The resins produced have good settled bulk density (27 to 36 lb/ft³ (430 to 580 kg/m³)) and the fines (defined as finer than 120 Mesh) were less than 5%.

- 21 -

Table 1 gives the results. An analysis of the results in Table 1 demonstrates:

1. Tests 1 and 2 indicate that the Melt Index of the product unexpectedly decreases with increasing temperature.
- 5 2. Tests 3 and 4 reconfirm the effect of temperature with a different catalyst formulation which is about three times more active (about one third ash, Al and Zr).
3. Tests 5 and 6 indicate that, as expected, the MI increases as a result of increasing the hexene gas ratio. However,
10 further increase in hexene gas ratio to make low density (test 7) actually decreased melt index, which is unexpected. The difference in ethylene partial pressure between tests 7 and 6 does not explain the MI change. An ethylene partial drop from 206 psi (1.42 MPa) to about 125
15 psi (0.861 MPa) is required to increase MI from 4.1 (test 7) to 7.1 (test 6).
4. Tests 7 and 8 indicate that MI drops significantly, and unexpectedly, with injection of isopentane into the reactor. This finding is very significant because this
20 gives an effective way of reducing MI to about 1 without using a temperature increase which can be detrimental to good reactor operation for low density products.
5. Oxygen reduces MI (compare tests 9 and 10 with 7). Also, addition of oxygen in combination with isopentane (test
25 12) can give fractional MI resin. This result is unexpected, particularly because the catalyst contains aluminum alkyl. Any oxygen addition was expected to be scavenged by the aluminum alkyl before modifying the catalyst site.
- 30 6. Water is found to increase MI (compare tests 7 and 11). This result is unexpected since the catalyst contains aluminum alkyl. Any water addition was expected to be scavenged by the aluminum alkyl before modifying the catalyst site.
- 35 In addition to isopentane, oxygen and water, other additives were explored, such as TIBA, carbon dioxide, carbon monoxide and acetylene. The results indicated TIBA increases

- 22 -

MI, CO₂ and CO decrease MI while acetylene does not have a significant effect. However, all these modifiers do not have the same impact on the catalyst activity in achieving similar changes in MI.

5 The results are given in Table 2. An analysis of the results in Table 2 demonstrates:

1. Tests 1 and 2 show TIBA increases MI significantly. In addition, the activity of the catalyst increased significantly in the presence of TIBA (compare the
10 Zirconium ppm in the product). Preliminary tests using other electron withdrawing compounds such as TMA and TEAL indicate all of these compounds may not effect the MI similarly on this catalyst.
2. Tests 3 and 4 compared with 2 show that carbon dioxide
15 reduces the MI with this catalyst, which is not expected from the effect of carbon dioxide on other catalysts. Similarly, tests 5 and 6 compared with 2 show carbon monoxide also reduces MI. However, the catalyst activity drops significantly more with carbon monoxide compared to
20 the effect of carbon dioxide (compare 4 and 6).
3. Unlike the results reported in Table 1, where we could make 1 MI using isopentane alone (test 8, Table 1), addition of a modifier was necessary along with isopentane while doing tests reported in Table 2. We believe this is
25 due to difference in the background level of modifiers.
4. Electron donating compounds, e.g. CO, CO₂, and electron withdrawing compounds, e.g., TIBA, can modify our
metallocene catalysts to change the resin MI. Other
electron donating compounds can be ethers, alcohol,
30 peroxides, ketones, esters, thioethers, carbonyls, amines, phosphines, phenols, etc. Other electron withdrawing compounds can be trialkylaluminum, alkyl aluminum chloride, trialkyl borane, etc. It is believed that these modifiers can also work in gas phase, slurry or high
35 pressure process.

Using these catalysts, preliminary product scoping in the fluid bed reactor has been carried out. As a result of the

- 23 -

unique combinations of isopentane, hexene, temperature and modifiers that were discovered in this work, it was possible to adjust MI and densities in a very broad range; ranging from 0.915 to 0.962 g/cm³ by varying comonomer level (hexene or 5 butene) and melt index ranging from 0.5 to 250 by varying the reactor temperature, ethylene partial pressure, isopentane, oxygen (or carbon dioxide, carbon monoxide) and hydrogen.

It is believed that significantly lower or higher melt index (less than 0.2 or greater than 500) materials can be 10 produced if necessary. Similarly, it is expected that products can be made with lower density than 0.915 g/cm³ (0.905 g/cm³ or lower) and with higher density than 0.962, if necessary.

Claims

1. A process for the polymerization of ethylene or the copolymerization of ethylene with an alpha olefin of 3 to 10 carbon atoms, produces resin having a MI (g/10 min.) value in the range of 0.0001 to 500, (wherein MI is , wherein the process comprises:

- 10 (a) fluidizing a particulate, activated supported metallocene catalyst, in a fluid bed gas phase reactor, wherein the catalyst comprises a support, a transition metal (M_{Tr}) and Al, wherein the amount of M_{Tr} (elemental basis) ranges from 0.001 to 10 weight percent, the amount Al (elemental basis) ranges from 1 to 40 weight percent and the Al: M_{Tr} ratio (elemental basis) ranges from 25 to 10000;
- 15 (b) contacting said catalyst with a feed selected from the group consisting of (1) ethylene, (2) ethylene admixed with hydrogen, (3) ethylene admixed with an alpha olefin of 3 to 10 carbon atoms, and (4) ethylene admixed with hydrogen and an alpha olefin of 3 to 10 carbon atoms, to produce polymerized product;
- 20 (c) maintaining a polymerization pressure of less than 1000 psi (6.9 MPa) and a polymerization temperature in the range of 55°C to 115°C;
- 25 (d) contacting the fluidized catalyst with a reagent to increase or decrease the MI of the polymerized product; and
- (e) recovering polymerized product.

30 2. A process according to Claim 1, wherein the reagent is isopentane and/or an electron donating compound to reduce the MI of the polymerized product.

3. A process according to Claim 2, wherein the isopentane is used at a partial pressure of from 2 to 80 psi (14 to 550 KPa).

4. A process according to Claim 2, wherein the electron

-27-

donating compound is used in an amount ranging from 0.01 to 500 ppm molar ratio to ethylene.

5. A process according to Claim 2, wherein the electron donating compound is selected from the group consisting of oxygen, carbon monoxide and carbon dioxide.
6. A process according to claim 2, wherein the isopentane is co-fed with the electron donating compound, which is selected from the group consisting of oxygen, carbon monoxide and carbon dioxide.
7. A process according to Claim 1, wherein the reagent is water or an electron withdrawing compound to increase the MI of the polymerized product.
8. A process according to Claim 1, wherein the support is silica, alumina or silica/alumina.
9. A process according to Claim 8, wherein the catalyst is in the form of porous amorphous particles having a particle size in the range of 1 to 500 microns which comprise silica, a M_{Tr} and Al, wherein the Al: M_{Tr} ratio ranges from 70 to 350; wherein said silica has a pore volume of 0.1 to 5 cm³/g, and has a concentration of hydroxyl groups in the range of 0 to 2.5 mmole/g of silica; wherein said catalyst is prepared, in activated form, by contacting said silica with a volume of a mixture comprising a metallocene and an alumoxane, wherein said volume of said mixture is no greater than the total pore volume of said dehydrated silica; wherein said metallocene has a formula, $Cp_mMA_nB_p$, wherein Cp is a substituted cyclopentadienyl group; m is 1 or 2; M is zirconium or hafnium; and each of A and B is selected from the group consisting of a halogen atom, a hydrogen atom, an alkoxyl group and an alkyl group, providing that $m+n+p$ is equal to the valency of the metal M; wherein said alumoxane has the formula $R-(Al(R)-O)_n-AlR_2$ for oligomeric linear alumoxanes, or has the formula $(-Al(R)-O)_m$ for

-28-

oligomeric cyclic alumoxane, wherein n is 1-40, m is 3-40, and R comprises a C₁-C₈ alkyl group.

10. A process according to Claim 9, wherein the metallocene is
5 selected from the group consisting of bis(n-butylcyclopentadienyl)metal dihalides, bis(n-butylcyclopentadienyl)metal hydridohalides, bis(n-butylcyclopentadienyl)metal monoalkyl monohalides, bis(n-butylcyclopentadienyl)metal dialkyls and bis(indenyl)metal
10 dihalides.

11. A process according to Claim 10, wherein the metallocene is bis(isobutylcyclopentadienyl) zirconium dichloride.

15 12. A process according to Claim 1, wherein said polymerization pressure is maintained at less than 400 psi (2.8 MPa).

BROOKHART, Maurice, S.; 944 Old Orchard Road, Chapel Hill, NC 27514 (US).			
(54) Title: α -OLEFINS AND OLEFIN POLYMERS AND PROCESSES THEREFOR			
(57) Abstract			
<p>Disclosed herein are processes for polymerizing ethylene, acyclic olefins, and/or selected cyclic olefins, and optionally selected olefinic esters or carboxylic acids, and other monomers. The polymerizations are catalysed by selected transition metal compounds, and sometimes other co-catalysts. Since some of the polymerizations exhibit some characteristics of living polymerizations, block copolymers can be readily made. Many of the polymers produced are often novel, particularly in regard to their microstructure, which gives some of them unusual properties. Numerous novel catalysts are disclosed, as well as some novel processes for making them. The polymers made are useful as elastomers, molding resins, in adhesives, etc. Also described herein is the synthesis of linear α-olefins by the oligomerization of ethylene using as a catalyst system a combination of a nickel compound having a selected α-diimine ligand and a selected Lewis or Bronsted acid, or by contacting selected β(a)-diimine nickel complexes with ethylene.</p>

C(Continuation) DOCUMENTS CONSIDERED TO BE RELEVANT

Form PCT/ISA/210 (continuation of second sheet) (July 1992)

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 96/01282

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☒ Claims Nos.: 395
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
Claim 395 is a product claim and refers back to claim 14, which is a process claim

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

SEE FURTHER INFORMATION SHEET

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☒ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

1. Claims : 1-25, 37-238, 243-344, 358, 359, 366 as far as they relate to claims 358, 367-394, 396-509, 510-520 and 523-527 as far as they relate to claims 358, 528-552, 554-562.
2. Claims : 26-36
3. Claims : 239-242
4. Claims : 345-357, 360-365, 366 as far as they relate to all mentioned claims except 358, 510-527.
